Method for parent-baby prevention

Description: Prevention in psychomotricity when working with babies and their parents is essential and multifactorial. The practitioner's attention is turned towards the baby and analyzes its development (motor, affective-social, cognitive). The psychomotor therapist appreciates the parents with their strengths, weaknesses and doubts, and reinforces and enhances their parenting skills.

Activity: A parent is wondering about the fact that her 13 months old child is not yet walking. The focus here is to analyze the state of development of the baby, to detect early signs of potential disorders, and in addition to give instructions on how to stimulate the baby, how to direct him along the way to physical movement, and to give value to the parental skills, while emphasizing the positive points observed.

Keywords: development, interaction, communication, motor skills
